

Schneider Electric's Critical Infrastructure and Security Practice (CISP) is a global leader in cyber security services, providing comprehensive security solutions.

Benefits

Our clients have requirements larger in scope than secure products alone can provide. We have a comprehensive solution portfolio that includes:

- Products designed with security
- Compliance with industry standards
- Cyber security experts and delivery/support personnel
- Enhanced solutions to meet client cyber security program needs

Our cyber security solutions will meet the challenging industrial landscape. We are the largest and most experienced ICS cyber security practice in the industry.

Advantages

- Platform Independent: CISP's security solution portfolio will work on ANY control system platform.
- Network Agnostic: CISP's security solution portfolio can be deployed on any network topology or technology, independent of network lifecycle, due to the lifecycle methodology of the solution portfolio.
- Industry Relevant: CISP's portfolio is applicable to any industrial manufacturing industry, whether the focus is on cyber security compliance or network systems optimization.
- Solution Ecosystem: CISP is greater than the sum of its parts: cyber security consulting, network compliance, regulatory experts, auditors, network systems design, and implementation.

Mining

The global metals, minerals, and mining industry represents not only variety of mining technologies and types, but also encompasses a vast amount of raw materials that are critical to the global manufacturing for both industrial and commercial goods. For these reasons, the mining industry has been identified as critical infrastructure by every global region. With its large reliance on automated control and SCADA systems and with mining

facilities considered globally to be the “least ready” to face cyber threats and attacks¹, it is vulnerable to cyber security threats as well as threats against safety. Protecting the metals, minerals, and mining industry from potential cyber security threats is key to not only limiting facility and system shutdowns but also limiting potential disruptions to operations that could result in endangering public safety through the water supply. These metals, minerals, and mining facilities require cyber security and with a revolving regulatory landscape, the first step towards securing these facilities is a comprehensive cyber security compliance program that identifies risks and needs. According to Ernst & Young's 2013 Global Information Security survey of mining and metals, there has been a 41 percent increase in external threats over the past year, with a 28 percent increase in cyber vulnerabilities.² And with 44 percent of organizations that do not have a threat intelligence program, it's no wonder where the risk lies.³

Fortunately, there are already many existing and evolving cyber security requirements and regulations that address cyber security compliance and can be easily adopted to any industrial landscape such as mining. However, many of these regulations are not prescriptive, leaving the individual operators with the overwhelming task of developing and implementing a cyber security program on their own. In most cases, this results in a reliance on singular hardware and software point solutions such as firewalls and anti-virus software—leaving them with a false sense of security. After all, who is going to install, configure, maintain, and patch these items? As with any project undertaking such as cyber security, the first step is to identify the risks to help define the needs that will ultimately identify the compliance requirements, providing the operators the key actionable items in the plan to move to the next step to identify their unique technical requirements and specifications. Simple point solutions are ultimately a “one size fits all” approach, when in fact every facility and plant owned by a single company is unique, requiring a plantwide comprehensive cyber security solution that is flexible enough to address any individual facility's needs.

Many companies may already be at some point in the development of a cyber security program or just embarking on the process. To facilitate these needs, the Schneider Electric cyber security consulting team has developed their portfolio of cyber security solutions using their Security Compliance Lifecycle Methodology. This approach permits the cyber security consulting team to engage with a client at any point in their own program's lifecycle. If the project is brand new, the cyber security consulting team would start with the Assessment stage. If it is mature and already in place, the cyber security consulting team can begin at the Management stage or any point between.

The security compliance lifecycle approach consists of these four tenets:

Assessment

The cyber security consulting team reviews the current network, identifies any problems or issues, and suggests areas for improvement.

Development

Using an assessment or plan as a guideline, the cyber security consulting team identifies what needs to be implemented and develops the detailed designs required to make it happen.

Implementation and Modernization

The cyber security consulting team takes the network design and turns it into reality through the procurement, staging, and commissioning of the client's new system or system upgrades.

Management and Optimization

The cyber security consulting team manages the network closely, providing a mechanism to improve and optimize the continuously changing landscape of network usage.

The Schneider Electric cyber security consulting team is a global consulting organization that provides comprehensive cyber security compliance and solutions regardless of industry. The cyber security team's solutions are system- and plant-agnostic and are adaptable to any industry and region.
